This paper is a result of the IES project funded by the Austrian Climate and Energy Fund, administrated by the Austrian Research Promotion Agency (FFG) under contract number 853693. It has been prepared in the course of work-packages two, three and four to outline the big picture and to identify the different interoperability issues of smart energy systems. The editors would like to thank all the contributing team members of the IES project for their invaluable contribution of knowledge, experience and support toward a better joint understanding of the complexities involved in safe and smart energy systems.

1 About the Document

1 A **Technical Framework** represents a technical specification, which is integrated into a predefined
2 document structure. Please note that a technical framework does not equal a new standard. It rather
3 describes the normalised use and application of existing standards and practices to avoid
4 interoperability issues. Integration Profiles state constraints/recommendations that define how to
5 apply standards and good practice to realise a specific feature of a Business Function in an important
6 interoperability fashion. The technical framework is embedded in a business domain overview, which
7 is accessible from the project homepage at <http://www.iesaustria.at>. The concept is based on the IHE
8 technical framework that subdivides a technical framework into two part: volume 1 for an informative
9 and volume 2 for a normative description. This document describes volume 2.

10
11 The document structure of the technical framework is as follows:

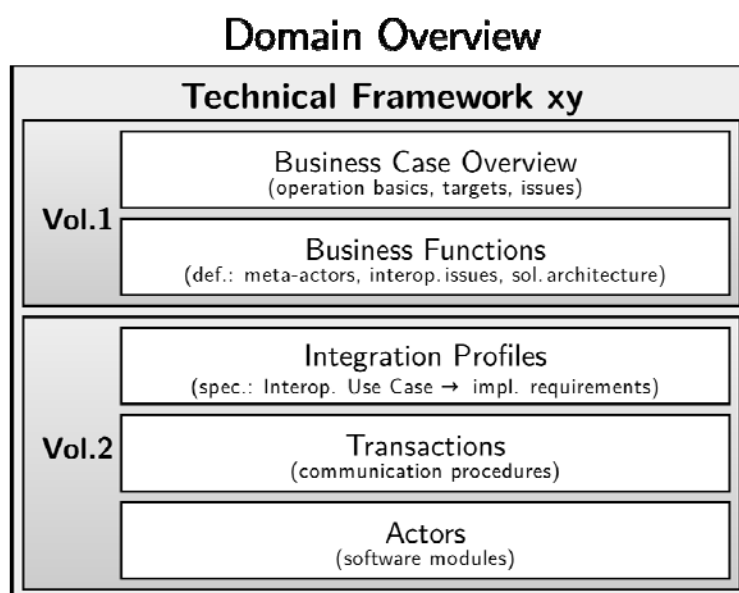

12 13 **Volume 1:**

- 14 • Business Case Overview (informative)
 - 15 ▪ Typical use cases
 - 16 ▪ Relevant meta-actors
 - 17 ▪ Related standards
- 18 • Business Functions (informative)
 - 19 ▪ Describe the interoperability issues with the IEC 62559 Use Case Methodology
 - 20 ▪ Use Case diagrams

21 **Volume 2:**

- 22 • Integration Profiles (informative and normative)
 - 23 ▪ Technical solution for a specific interoperability issue from the Business Function
 - 24 ▪ Definition of transactions that are needed
 - 25 ▪ Definition of actors that are involved
- 26 • Transactions (normative)
 - 27 ▪ Specification of actors that shall be implemented
 - 28 ▪ Specification of the IT standards and how options/variants shall be used

29

30

31

Figure 1: Structure of the Document (IES Technical Framework Template)

2 Definitions

32 **Actor**

33 is a functional software component of a system that executes transactions with other actors as defined
34 in an Integration Profile.

35

36 **Business Case**

37 is the economic viable application of an idea or technology.

38

39 **Business Function**

40 is a feature required to be realised for a Business Case to work.

41

42 **Conformance Testing**

43 is a standalone process to ensure that the implementation conforms to specified standards and
44 profiles, i.e. the implementations outputs and response are checked against rules and patterns.

45

46 **Integration Profile**

47 is the specification required to realise a part of a Business Function (or combination thereof) in an
48 interoperable fashion (normalised).

49

50 **Interoperability Testing**

51 is a process to check whether the system interacts effectively with foreign systems, i.e. when different
52 vendors meet to test their interfaces against each other (e.g. Connectathon).

53

54 **Interoperability Use Case**

55 is a (part of a) Business Function that relies on data exchange between different actors according to
56 an Integration Profile (i.e. where interoperability is required).

57

58 **Meta-Actor**

59 is the composition (grouping) of all the functional components (actors) that the Meta-Actor is required
60 to integrate in order to perform all the Business Functions related to it (according to the Use Case
61 Diagram). It could be a human operator, but typically it is a software component embedded in some
62 device that provides an interface to some communication infrastructure.

63

64 **Transaction**

65 is the specification of a set of messages (1..n) exchanged between at least two actors that realise the
66 Use Case specific information exchange (in one or both directions, in a strict or loose order) as specified
67 by an Integration Profile.

68

69 **Operational Use Case**

70 is a (part of a) Business Function that describes an activity not involving any data exchange between
71 actors. Operational Use Cases are mentioned in the Technical Framework, but not considered by
72 Integration Profiles because per se they do not raise interoperability problems.

73

3 Integration Profile: Send Planned Schedule

74 The profile “Send Planned Schedule” describes the interoperability issue for exchanging control
 75 information among the central Virtual Power Plant Operator (VPPOP), local Distributed Energy Unit
 76 Operators (DEUOPs) and the different Distributed Energy Unit Controllers (DEUCs) executing the
 77 contribution of the different Distributed Energy Units (DEUs) to the Virtual Power Plant (VPP). The
 78 content of the exchanged information depends on the Business Function, see the descriptions in
 79 Volume 1. The format of the exchanged information and the exchange per se are specified by the used
 80 standard series IEC 61850. The different communication relations and the used communication
 81 standard lead to the following actors-transactions relations in Figure 2 which are introduced in this
 82 Section. The concrete implementation strategy of the transactions is described in Section 4.

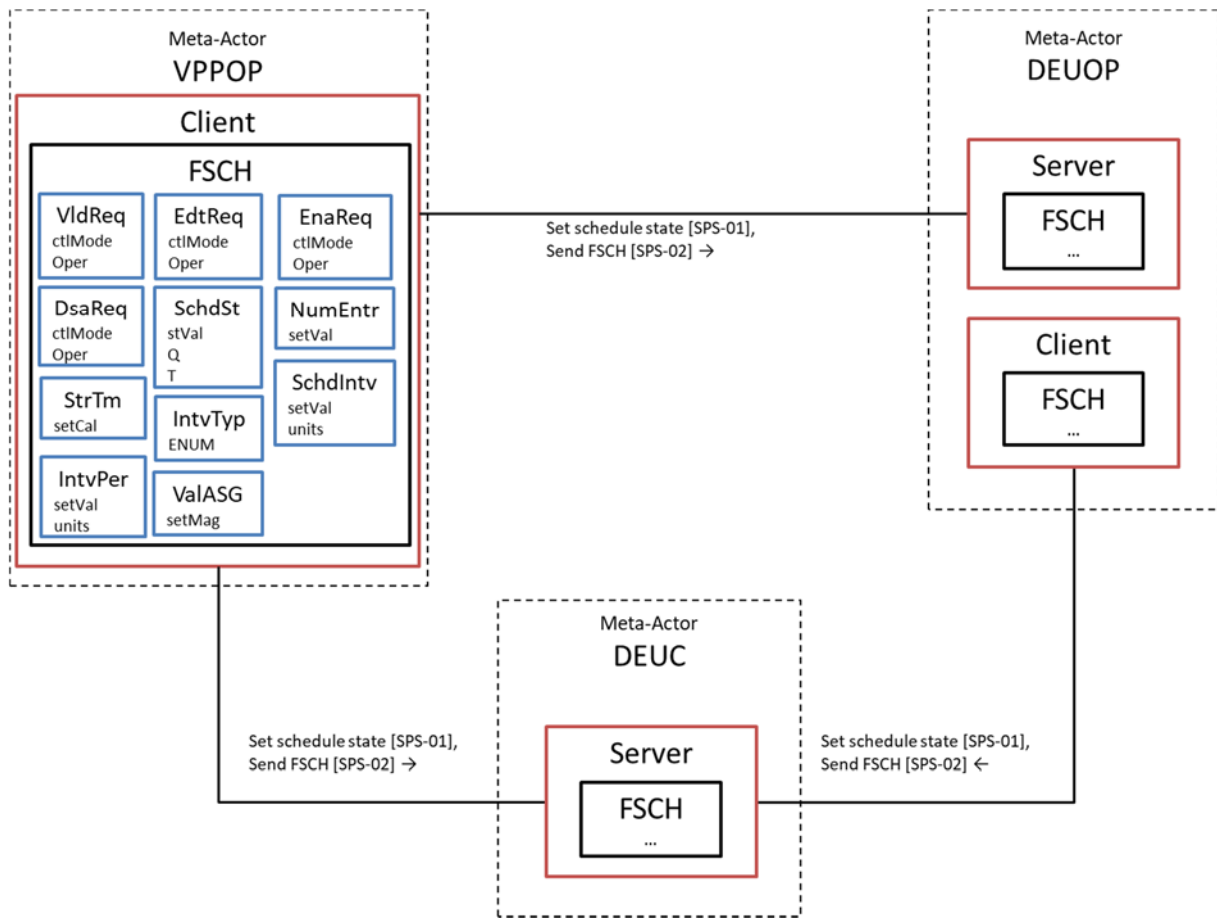

83 The following table specifies the mandatory actor grouping for the Integration Profiles defined in this
 84 document. Where possible, already defined and approved Integration Profiles from IHE are
 85 referenced. The IHE Integration Profiles can be found at <http://www.ihe.net>.

86 Table 1: Dependencies among Integration Profiles (bundling with external IPs)

Integration Profile	Depends on	Dependency Type	Purpose
61850 Send Planned Schedule (SPS)	IHE - Consistent Time	Each SPS Actor shall be grouped with the IHE Time Client Actor	To ensure consistency among timestamps
61850 Send Planned Schedule (SPS)	IHE – Audit Trail and Node Authentication	Each SPS Actor shall be grouped with IHE Secure Node or IHE Secure Application Actor	Required to manage audit trail of exchanged messages, node authentication and transport encryption
61850 Send Planned Schedule (SPS)	Set/Get 61850 Data Attribute/Object	Each SPS Actor shall transmit data attributes/objects to another actor	Transmitting the content of the LN from client to server or vice versa
61850 Send Planned Schedule (SPS)	Establish a secure connection	Client shall initiate a secure connection with the server.	Communication via a secure path
61850 Send Planned Schedule (SPS)	Check 61850 server status	Client requests the LD status of the server.	Precondition to check whether the LD is in the right state for the further transactions.

87

88 **3.1 Actors/Transactions**

89
90 Figure 2: Actors/Transaction Diagram for Send FSCH: The dashed lines represent the grouping
91 of actors into meta-actors.

92 Table 2: Transactions for Send Planned Schedule

Actors	Transaction	Optionality	Section
Client	Set schedule state [SPS-01]	R	4.1
Server	Set schedule state [SPS-01]	R	4.1
Client	Send FSCH [SPS-02]	R	4.2
Server	Send FSCH [SPS-02]	R	4.2

93
94 Hint: The DSCH was removed by the IEC 61850-7-4 (2016) and is fully replaced by the FSCH. Therefore,
95 no transactions and profiles for the DSCH are created.

96 **3.1.1 Actor Descriptions and Actor Profile Requirements**

97 Some of the meta-actors/actors definitions are available in Section 3 of Volume 1.

98 **3.1.1.1 Client**

99 The Client is the actor that initiates a communication over a TPKT channel, being a “Transport Service
100 on top of the TCP (IETF RFC 1006), to the Server. Either it wants to send some information, or it
101 wants to request some information. If a TPKT channel to the Server is not already established, it
102 initiates the connection setup with the Integration Profile “Establish a secure connection” and
103 applies the bundled IHE ATNA Integration Profile to assure secure authorisation, encrypted data
104 transport and adequate logging options.

105 **3.1.1.2 Server**

106 The Server honours the request from the Client by contributing to the connection setup, receiving
107 the sent message, responding adequately to the received message. The Server either simple receives
108 the sent information or response to a received request. Latter can be the execution of an internal
109 task or replying some information to the Client via message in return.

110 **3.1.2 Transactions**

111 **3.1.2.1 Set schedule state**

112 The LN FSCH (functional schedule) of the standard series IEC 61850 has control data objects to
113 change the state of the schedule. With these data objects, the schedule state shall be set to “Not
114 ready” before new values for the schedule can be transmitted. The data objects are mapped to a SCD
115 structure for representing the LN control unit. After establishing a secure connection via TLS 1.2, the
116 data transmission takes place from the client (VPPOP/DEUOP) to the server (DEUC); it depends on
117 the Integration Profiles “Establish a secure connection” and [Set/Get 61850 Data Attribute/Object](#).

118 **3.1.2.2 Send FSCH**

119 After setting the schedule state to “Not ready”, the data objects of the functional schedule (LN FSCH)
120 are transmitted via the secure TLS 1.2 connection. The data objects are mapped to a SCD structure for
121 representing the LN settings of the FSCH. The transmission is initiated by the client (VPPOP/DEUOP)
122 that writes the data objects for the schedule in the SCD file of the server (DEUC); it depends on the
123 Integration Profiles “Establish a secure connection” and [Set/Get 61850 Data Attribute/Object](#).

124 **3.2 Actor Options**

125 Options that may be selected for each actor in this profile are listed in Table 3. Afterwards, the options
126 are described and dependencies between options are specified.

127 Table 3: Actor Options for Send Asset Configurations

Actor	Role	Option	Vol. & Section
VPPOP	Aggregator	Market participant	Vol. 2, 3.2.1
	Operator (Client)	Plant Operator	Vol. 2, 3.2.2
DEUOP	Controller (Server)	DEU Controller	Vol. 2, 3.2.3
	Operator (Client)	Station Operator	Vol. 2, 3.2.4
DEUC	Controller (Server)	DEU Controller	Vol. 2, 3.2.3
DEU	Technical Unit	Producer	Vol. 2, 3.2.5
		Consumer	Vol. 2, 3.2.6
		Storage	Vol. 2, 3.2.7

128

129 **3.2.1 Market participant**

130 The VPPOP commonly acts as a market participant on the energy market, e.g. using the CIM standard
131 series (IEC 62325) to negotiate and sell schedules (energy production cycles) and ancillary services (grid
132 friendly flexibility). VPP focused on selling the aggregated energy volumes produced by the many
133 assets it joins on the energy market (EX – energy exchange) is called commercial VPP (cVPP), whereas
134 a VPP focused on selling ancillary services to the distributed grid operators (DSOs – distributed system
135 operators) that their assets are connected to, is called technical VPP (tVPP). In practice, with today’s
136 governed energy pricing, a more or less balanced mixture of the two is the economically most viable
137 VPP operation approach.

138 3.2.2 Plant Operator

139 The VPPOP manages many small assets and integrates them into one large virtual asset that is big
140 enough to participate in the energy market. Every traditional plant operator is bound to the contracted
141 grid access limits bought from the DSO. A VPP plant operator is bound to the contracted grid access
142 limits bought per asset from the relevant DSO the asset is connected to. These limits are considerably
143 smaller as they apply for inserting energy in the medium to low voltage distribution grids. However,
144 the distributed connection of the many assets of a VPP to the energy grid enables the VPP operator to
145 provide ancillary services that help the DSOs to balance their regional grid. In that case the DSO can
146 call negotiated local schedule adjustments from the VPPOP, i.e., access flexibility that helps him in
147 balancing his grid. The regulative alternative for DSOs, which is commonly in place as last resort
148 measure, is selective disconnection of individual assets. Compared thereto, are ancillary service far
149 more granular but require active cooperation of the plant operator.

150 3.2.3 DEU Controller

151 The DEU Controller (DEUC) provides the intelligent interface that converts DEU hardware into a
152 digitally accessible IED, which can communicate with other entities. In case the DEU is integrated in a
153 locally managed group of different assets, the DEUC communicates with the DEUOP. In case the DEU
154 is integrated directly into a VPP, the DEUC communicates with the VPPOP. In any case, the DEUC
155 translates messages received into control signals that make the hardware perform as intended and
156 converts sensor signals into data objects and attributes that can be forwarded to control instances
157 (i.e., a DEUOP and/or VPPOP). A DEUOP that is managed by a VPPOP represents the entire group of
158 assets it manages as a single virtual DEU. Therefore, it can have the DEU Controller role alike a DEUC.
159 The internal mechanisms to merge features and characteristics of many assets into a single
160 representation may be complex but seen from the VPPOP the DEUOP appears alike a DEUC. However,
161 requests from the VPPOP need more time to be answered because the DEUOP first needs to derive
162 required requests per asset, than send these to according DEUCs and process the answers it received
163 before it can send an answer to the VPPOP.

164 3.2.4 Station Controller

165 Alike traditional plant operators and prosumers can a DEUOP act as a local plant operator and offer
166 ancillary services to its DSO, independent of its integration in a VPP. It does this autonomously by
167 optimally controlling local assets it manages solely according to targets specified by its owner. In
168 general, a DEUOP does not take part on the EX because the joint local assets are too small; this is the
169 part of the VPPOP as aggregator. The managing actor of a micro-grid is for example such a station
170 operator, but also every smart home/building management actor that can control how and when
171 energy is produced and consumed by which device in the house/building. Selling energy on the EX and
172 providing ancillary services to DSOs are more general Business Functions not only available to VPPs,
173 and shall be specified independent of the Technical Framework on VPPs. Later, the according actors –
174 specified somewhere else – shall be bundled to the respective VPP actors of Table 3 to prevent that
175 VPPs require different solutions than those other entities use for identical tasks.

176 3.2.5 Producer

177 DERs occur as energy producers inserting an unknown schedule if not managed. Controlled by a DEUC
178 the behaviour can be managed such that they at least intend to fulfil a planned schedule. In case of RES
179 (renewable energy resources) the produced energy fluctuates due to environmental conditions (wind,
180 clouds, temperature, season, etc.). Such energy sources can be upper bound in the amount they
181 maximally produce, but a lower bound stating a minimum of energy produced is not always possible.

182 3.2.6 Consumer

183 Loads occur as energy consumer causing an unknown load schedule. Controlled by a DEUC the
184 behaviour can be managed such that they intend to fulfil a planned schedule. Heavy machines that can

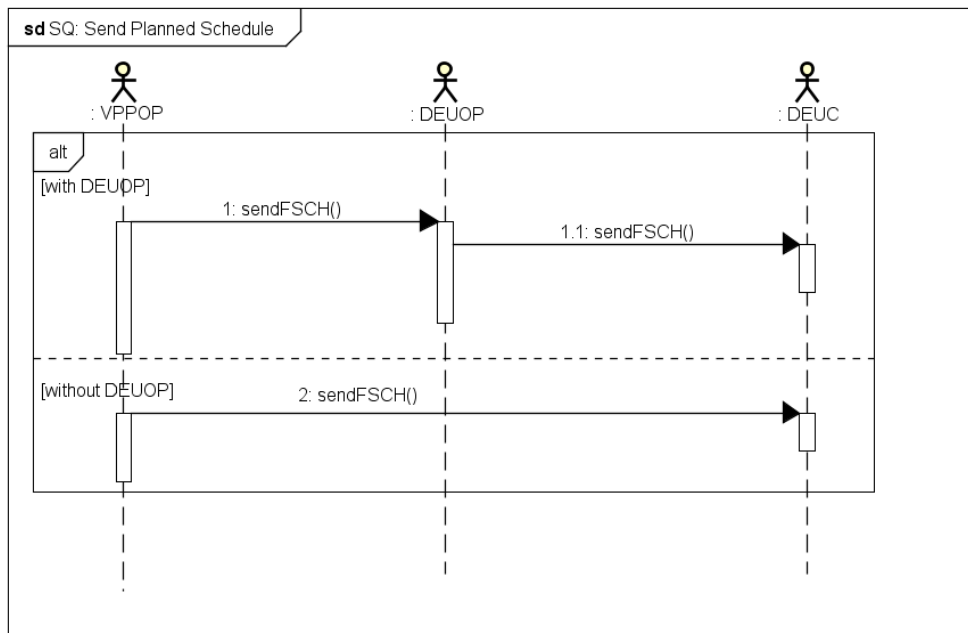

185 operate at different power levels and heating devices are among others common controllable loads
186 where a small difference in power consumption has marginal effect on the comfort of the user.

187 3.2.7 Storage

188 Energy Storages can occur as both, energy consumer and energy producer. Storage devices are
189 commonly somehow controlled by some actor. Controlled by a DEUC they become an IED that can be
190 integrated in a managed group of DEUs. Being designed as energy buffers their energy consumption
191 and production can be actively varied in a wide range, making them extremely valuable balancing
192 assets. Either as buffer for the volatile energy produced by RES, where the target is to keep the in
193 average stored energy minimal to have maximum headroom, or as energy reserve to cover energy
194 shortage, where the target is to keep the in average stored energy maximal to have maximum reserve.

195 Information Flow Process

196 The transmission of the planned schedule between the VPPOP or DEUOP and the DEUCs follows a
197 sequence of single transactions between the VPPOP, DEUOP and DEUC as described above. The
198 process flow is shown in Figure 3. The detailed description of the transactions, their data objects and
199 common data classes can be found in the specification of the Transaction "Send FSCH" in Section 4.

200

powered by Astah

201

Figure 3: Sequence Diagram for "Send Planned Schedule"

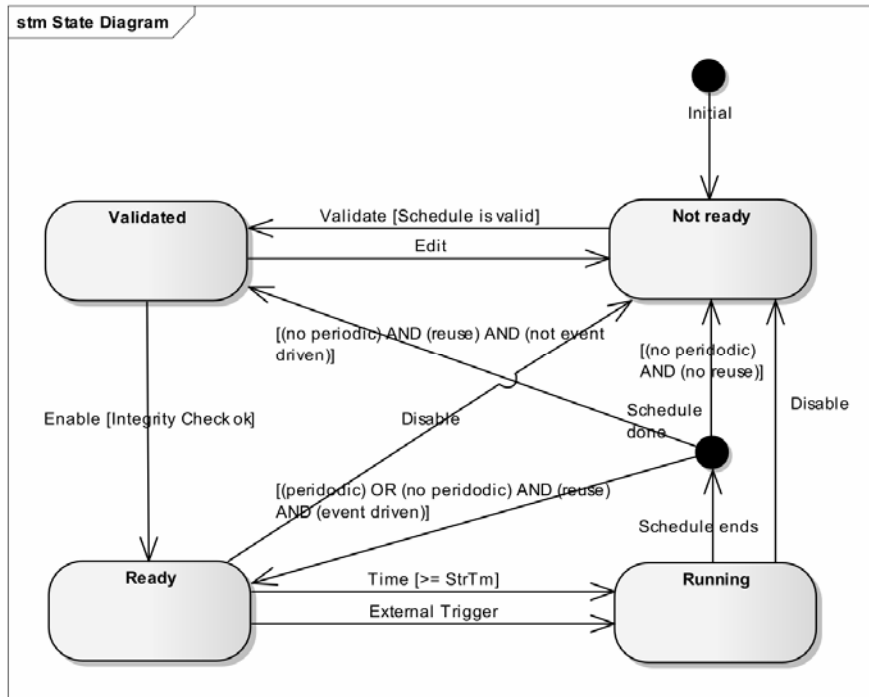

202 3.3 Implementation Strategies

203 Generally, the basics of the 61850 standard series shall be applied (described in the Intro of Vol. 2).
204 Additional details for the schedule exchange are described below.

205 3.3.1 State diagram for the schedule

206 As mentioned above, the IEC 61850 has defined the LN *functional schedule (FSCH)* for determining the
207 process of a schedule. A schedule can be in different states as shown in Figure 4: "not ready",
208 "validated", "ready" or "running". The state is set by the data objects VldReq, EnaReq, EdtReq, and
209 DsaReq of the LN FSCH. The schedule can only be edited in the state "not ready", i.e. if a schedule is in
210 state "validated", the state shall be changed to "not ready" with the data attribute EdtReq; otherwise,
211 the schedule shall be disabled with DsaReq to reach the state "not ready". Therefore, the Booleans of

212 the data attributes shall be set according to the schedule state that shall be reached. Before, the
 213 schedule can be activated, it shall be validated and set to the state “ready”. The activation of the
 214 schedule only depends on an external trigger or the time stamp that was set in the schedule.

215
 216

Figure 4: FSCH State Machine

217 3.4 Communication Requirements

218 The message type within the Integration Profile “Send Planned Schedule” is a Low speed message
 219 (Type 3, cf. IEC 61850-5). The message contains complex messages that shall be time-tagged. The
 220 message type should be used for slow speed auto-control functions, transmission of event records, or
 221 reading or changing set-points. In doing this, the transmission shall be less than 500 ms with TCP/IP.
 222 Thus, time-tagged schedules may belong to this type because the transmission is not time-critical for
 223 schedules which were negotiated on the Energy Exchange the previous day.

224 To utilize better timing GOOSE packs control information directly into Ethernet frames, skipping the
 225 TCP/IP layers. This is a different, better method that can be used within the reach of a LAN. A better
 226 implementation of the same information exchange, perfectly applicable for DEUOP – DEUC
 227 transactions.

228 3.5 Security Considerations

229 General security considerations are mentioned in the IEC 61850 basics (cf. Section 4.1.3 in the
 230 Technical Framework VPP Vol. 2).

4 Transactions

231 The transactions describe a concrete implementation of the interoperability issue described in the
232 Business Function in Volume 1 of the Technical Framework which were specified through the
233 Integration Profiles in Volume 2. The interoperability issues are described in each transaction as brief
234 interoperability use cases which demonstrate the challenge and the actors involved of the transaction.

235 The IEC 61850-7-3 gives an overview on the common attribute types and the common data objects
236 which are linked in the LN description of the 61850-4-720 part. The common data classes specify status
237 information, measured information, control information, status settings, and analogue settings. With
238 these data, a well-structured data exchange between substations, power plant and control centres,
239 and DEUCs can be described. Thus, the parts IEC 61850-7-2, IEC 61850-7-420, and IEC 61850-7-3 are
240 essential for implementing the communication mechanisms between devices from the power grid
241 domain, especially the asset setting, schedule exchange, and measurement values.
242

243 4.1 Transaction: “Set schedule state”

244 4.1.1 Scope

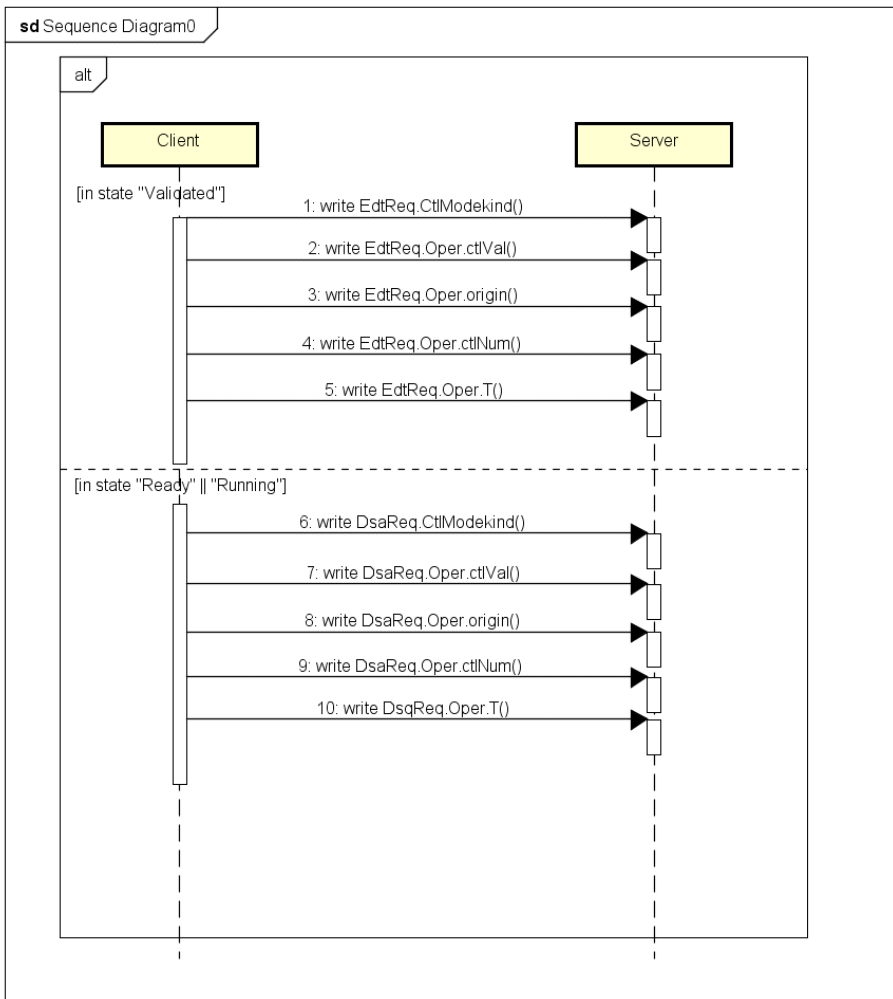

245 The VPPOP/DEUOP shall change the schedule state to enable the transmission of a new schedule.
246 Therefore, the schedule has to be in the state “not ready”. Prior the LD state of the server has to be
247 checked; it shall have the behaviour state “on” and the health state “OK”. The LD state is requested by
248 the VPPOP/DEUOP client and is specified in the functional Integration Profile [“Check status of the
249 server”](#).

250 4.1.2 Actor Roles

Role	Description	Actor
Client	The client is the transaction initiator that starts and sends or requests the values of the SCD file to a receiving server actor via TCP/IP. If specified, the client uses the IHE ATNA profile to establish a secured connection before the data transmission actually starts, if it is not already in place.	The following actors may play the role of the client: VPPOP, DEUOP
Server	The server is the transaction responder that receives the values of the SCD file or the request. In case a secure connection is required, it cooperates with the client in establishing security.	The following actors may play the role of the server: DEUOP, DEUC

251 4.1.3 Referenced Standards

- 252 • IEC 61850-7-420 (logical nodes)
- 253 • IEC 61850-7-2 (data objects, services)
- 254 • IEC 61850-5 (protocol requirements)
- 255 • IEC 62351 – TLS 1.2

257

powered by Astah

258 **4.1.4.1 Create message**

259 4.1.4.1.1 Triggering Event

260 The VPPOP/DEUOP wants to edit the schedule and has to set the schedule state to “Not ready”.

261 Therefore, the LD has to be in the status *on* and the health state *Ok*.

262 4.1.4.1.2 Message Semantics

263 Table 4: FSCH Data Object

Logical Device	Logical Node	Data Object	Common data class	Data Attribute	Functional Constraint	Description
VPPOP / DEUOP / DEUC	FSCH	VldReq	SPC	ctlModel	CF	Specifies the control model for validate transition request, possible values are: status-only, direct-with-normal-security, sbo-with-normal-security, direct-with-enhanced-security, sbo-with-enhanced-security

		EnaReq	SPC	ctlModel	CF	Specifies the control model for enable transition request, possible values are: status-only, direct-with-normal-security, sbo-with-normal-security, direct-with-enhanced-security, sbo-with-enhanced-security
		EdtReq	SPC	ctlModel	CF	Specifies the control model for edit transition request, possible values are: status-only, direct-with-normal-security, sbo-with-normal-security, direct-with-enhanced-security, sbo-with-enhanced-security
		DsaReq	SPC	ctlModel	CF	Specifies the control model for disable transition request, possible values are: status-only, direct-with-normal-security, sbo-with-normal-security, direct-with-enhanced-security, sbo-with-enhanced-security

264

265 The content of the SCD file to set the state of the schedule includes:

```

266 <LNodeType InClass="FSCH" id="FSCH" desc="Schedule">
267   <DO name="VldReq" type="SPC"/>
268   <DO name="EnaReq" type="SPC"/>
269   <DO name="EdtReq" type="SPC"/>
270   <DO name="DsaReq" type="SPC"/>
271 </LNodeType>
272 <DOType cdc="TSG" id="SPC">
273   <DA name="ctlModel" bType="Enum" type="CtlModelKind" fc="CF" dchg="true"/>
274   <DA name="ctlVal" bType="BOOLEAN" type="BOOLEAN"/>
275   <DA name="origin" bType="Originator" type="Originator" fc="ST" />
276   <DA name="ctlNum" bType="INT8U" type="INT8U" fc="ST" />
277   <DA name="T" bType="TimeStamp" type="TimeStamp" fc="ST" />
278 </DOType>
279 <EnumType id="CtlModelKind">
280   <EnumVal ord="0">status-only</EnumVal>
281   <EnumVal ord="1">direct-with-normal-security</EnumVal>
282   <EnumVal ord="2">sbo-with-normal-security</EnumVal>
283   <EnumVal ord="3">direct-with-enhanced-security</EnumVal>
284   <EnumVal ord="4">sbo-with-enhanced-security</EnumVal>
285 </EnumType>

```

286 4.1.4.1.3 Expected Actions

287 The VPPPOP/DEUOP has created the SCD file for setting the schedule state to “Not ready”.

288 4.1.4.2 Establish Secure Connection

289 A secure connection between client and server is established by the functional Integration Profile
290 “Establish a secure connection”.

291 **4.1.4.3 Transmit Message**

292 The Client writes the values of its SCD file to the SCD file of the Server via the secure TCP/IP
293 connection that was established in the step 4.1.4.2. The data transmission is specified in the
294 functional Integration Profile [Set/Get 61850 Data Attribute/Object](#).

295 **4.1.5 Security Considerations**

296 General security considerations are mentioned in the IEC 61850 basics (cf. Section 4.1.3 in the
297 Technical Framework VPP Vol. 2).

298 **4.2 Transaction: “Send FSCH”**

299 **4.2.1 Scope**

300 After the participation on the energy market and the coordination with the DSO according to the
301 planned schedules, the VPPPOP creates functional schedules for its DEUs and sends them to the DEUOPs
302 or directly to the DEUCs. The DEUOPs manage different DEUs and is responsible to execute the
303 schedules in the operative mode, i.e. the DEUOP creates single functional schedules for the different
304 DEUs and sends them to the DEUCs. The interoperability issue is the direct schedule exchange between
305 VPPPOP and DEUOP, VPPPOP and DEUC, and DEUOP and DEUC via a secure connection. Before, the
306 transaction of the schedule can be executed, the VPPPOP/DEUOP has to create the SCD file which will
307 be transferred to the DEUOP/DEUC.

308

309 Hint: The DSCH was removed by the IEC 61850-7-4 (2016) and is fully replaced by the FSCH. Therefore,
310 no transactions and profiles for the DSCH are created.

311 **4.2.2 Actor Roles**

312 Table 5: Actor Roles for Send FSCH

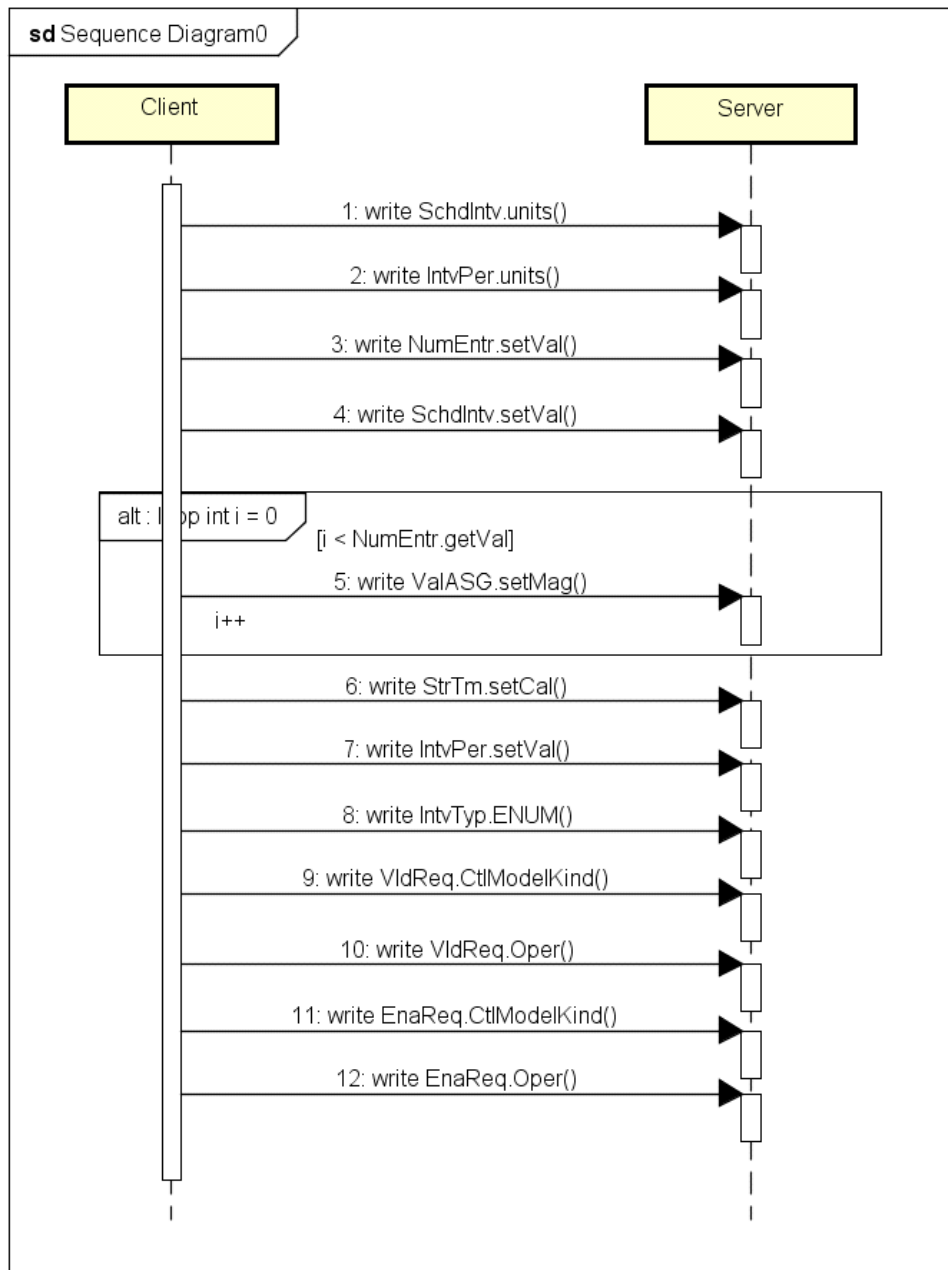

Role	Description	Actor
Client	The client is the transaction initiator that starts and sends or requests the values of the SCD file to a receiving server actor via TCP/IP. If specified, the client uses the IHE ATNA profile to establish a secured connection before the data transmission actually starts, if it is not already in place.	The following actors may play the role of the client: VPPPOP, DEUOP
Server	The server is the transaction responder that receives the values of the SCD file or the request. In case a secure connection is required, it cooperates with the client in establishing security.	The following actors may play the role of the server: DEUOP, DEUC

313 **4.2.3 Referenced Standards**

- 314 • IEC 61850-7-420 (logical nodes)
- 315 • IEC 61850-7-2 (data objects, services)
- 316 • IEC 61850-5 (protocol requirements)
- 317 • IEC 62351 – TLS 1.2

318 **4.2.4 Interaction Diagrams**

319 The interactions are depicted as sequence diagram. For the transaction “Send FSCH”, the sequence
320 diagram includes the transaction “Set schedule state” (as precondition) and the functional Integration
321 Profile [Set/get 61850 Data Attribute/Object](#) to transmit the values.

322
323

Figure 5: Data flow for Send FSCH

324 4.2.4.1 Create the message

325 4.2.4.1.1 Trigger Events

326 The VPPPOP triggers the transmission of the schedule including the FSCH LN to the respective
327 DEUOP/DEUC; otherwise, the DEUOP triggers the transmission to the DEUC. Therefore, the LD has to
328 be in the health state *Ok* and the schedule state of the LD has to be *not ready* (cf. Section 3.3) for
329 changing the schedule values in the next step (cf. Section 4.2.4.1.2).

330 4.2.4.1.2 Message Semantics

331 If the preconditions in the triggering event are fulfilled, the schedule can be edited by changing the
332 following data objects of the LN FSCH. The values of the SCD file from the LN are transmitted.

333 The schedule needs the following data objects from the FSCH (IEC 61850-7-420):

334 Table 6: FSCH Data Objects

Logical Device	Logical Node	Data Object	Common data class	Data Attribute	Functional Constraint	Description
VPPOP / DEUOP / DEUC	FSCH	SchdSt	INS	stVal	ST	State of this schedule
				Q	ST	Quality of schedule state
				T	ST	Timestamp of schedule state
		NumEntr	ING	setVal	SP	The number of schedule entries that are valid out of the instantiated ValASG. It shall be > 0.
		SchdIntv	ING	setVal	SP	The schedule interval duration
				units	CF	Eg.: sec, min, h, d
		ValASG	ASG	setMag	SP	The ASG scheduled values (current value output as MV (FC: Measured Value))
		StrTm	TSG	setCal	SP	Start time of the schedule in calendar time
		IntvPer	ING	setVal	SP	Interval period
				units	CF	Eg.: sec, min, h, d
IntvTyp	ENG	ENUM	SP	Interval type		

335

336 Notes:

337 FSCH: Functional schedule

338 ING: Integer status setting

339 ASG: Analogue setting

340 TSG: Time setting group

341 SP: setting point

342 EX: extended

343

344 Based on the LNs, a SCD file is generated with the IEC 61850 Substation Configuration Tool (SCT) by
 345 the H+S Hard- & Software Technologie GmbH & Co. KG. The SCD file shall content at least the
 346 following structure:

347

462

```

463 4.2.4.1.3 Expected Actions
464 The SCD content for the schedule is created by the VPPOP/DEUOP client.

465 **4.2.4.2 Establish Secure Connection**

466 A secure connection between client and server is established by the functional Integration Profile
467 “Establish a secure connection”.

468 **4.2.4.3 Transmit Message**

469 The client writes the values to the SCD file of the server via the secure TCP/IP connection that was
470 established in the step 4.2.4.2. The data transmission is specified in the functional Integration Profile
471 [Set/Get 61850 Data Attribute/Object](#).

472 **4.2.4.4 Validate LN FSCH**

473 The VPPOP/DEUOP client received a SCD file containing the functional schedule.

474 4.2.4.4.1 Trigger Events

475 The DEUOP/DEUC server received a message containing a schedule from the VPPOP.

476 4.2.4.4.2 Message Semantics

477 The SCD file described in Section 4.2.4.1.2 was transmitted and the same LN structure like in Table 6
478 shall result.

479 4.2.4.4.3 Expected Actions

480 The client got the LN FSCH data.

481 **4.2.5 Security Considerations**

482 For a secure transmission, a connection via TLS 2 (Transport Layer Security 2) is mandatory (cf. **Fehler!**
483 **Verweisquelle konnte nicht gefunden werden.**). Aspects for authentication/authorization and logging
484 as described the IHE ATNA Profile shall also be considered for this transaction:
485 http://wiki.ihe.net/index.php/Audit_Trail_and_Node_Authentication. The logging should contain
486 parameters of the transmitter, receiver, time-stamp, and status of the transmission (successful or
487 failing). Additional, reasons for the incorrect message transmission can be defined. A concrete schema
488 for the logging still has to be defined. The logging and the schema are specified in the Functional
489 Integration Profile “[Audit Trail Event](#)”.
